We can't journey to the centre of the Earth, but that hasn't stopped us finding out what is down there. The outer core is about 1, miles thick, and it's made mostly of a combination (called an alloy) of iron and nickel, along with small amounts of other dense elements like gold, platinum, and uranium. These metals can, of course, be found on the surface of Earth in solid form. Researchers from Australian National University (ANU) think they've determined that the Earth's core is most likely solid but a little.

For the first time, geologists have confirmed that our planet's inner core is indeed solid - although not quite as firm as previous models have. This occurs through both convective transport of heat within the earth's liquid outer core and solid mantle and slower conductive transport of heat through. A century ago, science barely knew that the Earth even had a core. Today we are tantalized by the core and its connections with the rest of the.

The inner core is a layer of the Earth at the very center of our planet. It is a solid ball made out of an iron-nickel alloy and other metals.

One day, about a billion years ago, Earth's inner core had a growth spurt. The molten ball of liquid metal at the center of our planet rapidly. The giant orb of iron and nickel that anchors Earth's center is spinning faster than the planet's surface, according to a new study that confirms. Earth's inner core is probably softer than previously thought. Seismologists from the Australian National University (ANU) have adapted a.
